## ION Science PID Gas Sensor Response Factors

### PID Gas Sensor Response

ION Science MiniPID 2 VOC gas sensors respond to a broad range of organic and a few inorganic gaseous and volatile chemicals ('volatiles'). For the PID sensor to respond to a volatile, the photon energy of the lamp must be greater than its ionisation energy (IE). Ion Science PIDs are available with lamps emitting light of maximum energy of 10.0 eV, 10.6 eV, and 11.7 eV. This Technical Article lists the response factors ('RF's') for over 900 volatiles with PID incorporating these lamps. The RF relates the sensitivity of PID to a volatile to the sensitivity to the standard calibration gas isobutylene. The higher the RF, the lower the sensitivity.

### Isobutylene as Reference Gas

Ideally, the PID response to a chemical volatile would be calibrated by using a low concentration of the chemical in air. However, this is often not practical. Isobutylene is then used to calibrate PID, and a Response Factor (RF) used to convert the isobutylene calibrated measurement to a measurement of the target volatile:

$$\text{Concentration of target chemical} = \text{isobutylene calibrated measurement} \times \text{RF}$$

For example, the RF of anisole is 0.59 with a 10.6 eV lamp. That means 0.59 ppm anisole delivers the same PID response as 1 ppm isobutylene. A 10 ppm response to anisole, from an isobutylene-calibrated unit would indicate:

$$\text{Concentration of anisole} = 10 \text{ ppm} \times 0.59 = 5.9 \text{ ppm}$$

### Compound Mixtures

The MiniPID 2 sensor will respond to all detectable volatiles present and it is not possible to measure the concentration of each individual component. When the formulation of a given mixture is known, the overall response factor for the mixture can be calculated as follows:

$$\text{RF} = 1/[X_1/\text{RF}_1 + X_2/\text{RF}_2 + X_3/\text{RF}_3 \dots]$$

where  $X_1$ ,  $X_2$ , and  $X_3$  are the mole fractions of components 1, 2, and 3, etc. For example, if a mixture consisted of 20% anisole (RF = 0.59), 30% acetone (RF = 1.17) and 50% ethanol (RF = 11), the overall RF would be:

$$\text{RF} = 1/[(0.2/0.59) + (0.3/1.17) + (0.5/11)] = 1.56$$

This factor can then be used to reconstruct the concentration of each component. For example, to measure worker exposure near a vat generating the above volatile mixture, the PID is calibrated with isobutylene and the response factor is set to 1.56. If the overall reading is 100 ppm, then the concentration of anisole is 20 ppm, acetone is 30 ppm, and ethanol is 50 ppm.

Often mixes are less well defined. Also, the fraction of each chemical component in a vapour depends on relative rates of volatilisation, saturated vapour pressure, temperature and so on. For personnel safety monitoring, it can then be advisable to

1. convert TWA and STEL ppm levels of each component to an equivalent isobutylene concentration. We shall call this *ppm iBueq*:

$$\text{TWA}_{\text{ppm iBueq}} = \text{TWA}_{\text{ppm}} / \text{RF}$$

$$\text{STEL}_{\text{ppm iBueq}} = \text{STEL}_{\text{ppm}} / \text{RF}$$

2. Adopt the lowest  $\text{STEL}_{\text{ppm iBueq}}$  and  $\text{TWA}_{\text{ppm iBueq}}$  for the PID detection of the vapour.

#### Concentration measurements of ppm vs mg/m<sup>3</sup>

All the RFs in this table apply to calibrated responses in units of ppm or ppb, normalised at 25°C and 1012 mbar pressure. The following equation allows conversion between ppm and mg/m<sup>3</sup>:

$$\text{Concentration (mg/m}^3) = \text{Concentration (ppm)} \times \text{molecular weight (g/mole)} / 24.5$$

#### PID Response Factor Table

Response factors for important chemicals are identified below. Chemicals are listed according to their most common name, but the CAS number should be used to more precisely identify each chemical.

The RFs of many chemicals have been measured at Ion Science typically with 10 and 50 ppm of the target volatile, using ten PIDs containing lamps of different photon energy and intensity and of different sensor designs. Generally, 50 ppm responses have been used. These RFs are indicated in **bold** in the table below.

The RFs in TA-02 are generally guideline figures for sensors and instruments manufactured by Ion Science. All RFs are subject to some variation due to differences in PID electrode stack design, UV light intensity and operating conditions. For the greatest accuracy, Ion Science recommends calibrating the instrument to the target gas at the concentration of desired measurement.

Particular care should be taken in measuring the PID response of gases at concentrations exceeding a few 1000 ppm as non-linearity of PID response varies between chemicals.

Caution should also be taken in making measurements at low concentrations of gas following exposure to concentrations which are 100's of times higher, due to the time required for sensor clear down.

Certain groups of volatiles have been identified, or are suspected, of causing temporary contamination of the PID window. Given the diversity of volatiles detected by PID, the end user should frequently calibrate, or bump test the PID application in its initial application to the sensing of less common volatiles.

In the table below, RF's listed as 'ZR' indicate zero response. 'NA' that the value is not available, because the PID response is insignificant at toxic concentrations of the volatile, or its RF is difficult to predict or measure.

The **Notes** column below identifies the following:

**S:** slow. PID requires at least 30 s for stable response.

**V:** Variable response. The response is susceptible to small changes in ambient conditions, particularly humidity.

**X:** Temporarily contaminating. PID responsivity may be suppressed for at least 30 min after 100 ppm-min exposure.

**W!**: Expected to cause PID lamp window fouling. May require regular bump tests and window cleaning.
